# McNamara's Cephalometric Analysis for Iraqi Population in Mosul City (Normal values of McNamara analysis in Mosul city) Abdulrahman Ibrahim Ali 

#### Abstract

Aims: The aims of this study are to establish normal values of Cl . I skeletal relationship and to assess ( Cl . II \& Cl. III skeletal relationships), in addition to the airway patency assessment based on McNamara's analysis in Mosul city for adult group of both genders.

Materials and Methods: This study was carried out on lateral cephalometric radiographs of total subjects (128) aged between (18-25) years old, Cl. I type ( 29 male and 26 female), Cl. II type ( 22 male and 19 female) and Cl. III type ( 17 male and 15 female), Steiner analysis (SNA, SNB and ANB angles) was used to differentiate subjects of Cl. I from those of Cl . II and Cl. III skeletal relationships. All lateral cephalometric radiographs were taken by (Kodak imagining 9000 C) machine, thirteen variables (angular and linear) of McNamara's analysis were analyzed digitally using (Kodak imagining software 9000 C ).

Results and conclusions: The results of this study showed significant statistical differences among three skeletal patterns. In Cl. I skeletal pattern, there was no significant difference in the position of maxilla in relation to cranial base between males and females, males had significantly longer mandible and larger facial axis angle, no significant differences found in midfacial length, lower anterior facial height, and mandibular plane angle in both genders, also no significant differences found between anterioposterior position of upper and lower incisors in both genderes.

Key Words: McNamara's analysis, Cephalometric analysis , Digital radiography and analysis.

## Introduction

One of the recent additions on cephalometric analysis is the McNamara analysis, this specific innovative analysis was introduced because a need had arisen for a method of analysis that is sensitive not only to the position of teeth within a given bone, but also to the relationship of jaw elements and cranial base structures one to another ${ }^{(1,2)}$. During the past years, clinical orthodontics has seen advent numerous orthognathic surgery procedures which allow three-dimensional repositioning of almost every bony structure in the facial region and of which presents new possibilities in the treatment of skeletal discrepancies ${ }^{(2)}$. This analysis is suitable not only for conventional orthodontic patients, but also for patients with skeletal discrepancies who are candidates for dentofacial orthopedics and orthognathic surgery ${ }^{(1,2)}$. McNamara analysis method is derived, in part, from the principles of the analyses of Ricketts and of Harvold, although other aspects, such as the construction of the nasion perpendicular and the point A vertical, are presumed to be original ${ }^{(2)}$.

The advantages of using McNamara's analysis are summarized below:

1. This method depends primarily upon linear measurements rather than angles, so treatment planning (particularly for the orthognathic surgery) is made easier.
2. This method of analysis is more sensitive to vertical changes than is an analysis which relies on the ANB angle (Steiner analysis). The use of the ANB angle can be misleading, since it tends to be insensitive to the vertical component of jaw discrepancies.
3. This analytical procedure provides guidelines with respect to normally occurring growth increments.
4. The principles of this analysis are easily explained to non specialists.

## This study aimed to:

1. Establishment of normal values of McNamara's cephalometric analysis for Cl . I skeletal relationship of Mosul city population.

## International Journal of Enhanced Research in Science Technology \& Engineering, ISSN: 2319-7463

Vol. 3 Issue 4, April-2014, pp: (287-299), Impact Factor: 1.252, Available online at: www.erpublications.com
2. Evaluation and comparison of Cl. I, Cl. II and Cl. III skeletal relations according to McNamara's analysis.
3. Estimation of gender differences between males and females in variables measured.
4. Assessment of airway patency depending on lateral cephalometric radiographs.

## Materials and Methods

Total samples of ( 128 subjects) were selected from lateral cephalometric radiographs of patients age between (18-25 years), and divided as follows:
Cl. I skeletal pattern group : 55 subjects ( 29 males and 26 females).
Cl. II skeletal pattern group : 41 subjects ( 22 males and 19 females).
Cl. III skeletal pattern group : 32 subjects ( 17 males and 15 females).

According to Steiner analysis (ANB angle), the samples were classified into three saggital skeletal classes as follows ${ }^{(3,4)}$ :
Cl. I : ANB $=0^{\circ}-4^{\circ}$.
Cl. II : ANB $>4^{\circ}$.
Cl. III : ANB $<0^{\circ}$.

Criteria of samples selection include: all the subjects and their parents were Iraqi in origin, born and lived in Mosul city, no history of orthodontic treatment, no TMJ problems, no history of oral habits, no facial asymmetry and full permanent dentition. Cases of open bite, cross bite and Cl. II division 2 malocclusions were excluded, all radiographs were taken in natural head posture while subjects close their teeth in centric occlusion and lips were in relaxed position ${ }^{(1)(5)}$. The lateral cephalometric radiographs were taken from patients attended to (ECHO specialized dental center) in Mosul city by using digital radiographic machine of high technology (Kodak imagining 9000 C ), while cephalometric analysis performed by using computer program (Kodak imagining software 9000 C) specific for cephalometric analysis.

The landmarks and reference lines for McNamara analysis as follows ${ }^{(2)}$, Fig.(1):

## A- Maxilla to Cranial Base:

1. NA-P perpendicular (nasion perpendicular to point A): A vertical line is constructed perpendicular to the Frankfort horizontal and extended inferiorly from the nasion. The perpendicular distance is measured from point $A$ to the nasion perpendicular.
2. SNA : The angle between the SN and NA lines.

## B- Mandible to Maxilla:

1. Co-Gn (effective mandibular length): A line is measured from the condylion to the anatomic gnathion.
2. Co-A (effective midface length): A line is measured from the condylion to point A.
3. MMD (maxillomandibular differences): Effective mandibular length minus effective midface length.
4. ANS-Me (lower anterior face height): A line is measured from the anterior nasal spine to the menton.
5. MD-P (mandibular plane angle): The angle between the anatomic Frankfort plane and the mandibular plane, gonion-menton.
6. FA-A (facial axis angle): A line is constructed from the basion to the nasion (NBa). A second line (the facial axis) is constructed from the posterosuperior aspect of the pterygomaxillary fissure (PTM) to the constructed gnathion (the intersection of the facial plane and the mandibular plane). The facial axis angle is the angle between the NBa and the facial axis.

## C- Mandible to Cranial Base:

1. $\quad$ Pg- N (pogonion to nasion perpendicular): The perpendicular distance is measured from the pogonion to the nasion perpendicular.

## D- Dentition:

1. Ui-A (upper incisor to point A): Point A perpendicular is constructed parallel to the nasion perpendicular through point A . The perpendicular distance is measured from the most anterior surface of the upper incisor to the point A perpendicular, Fig.(2).
2. Li-APg (lower incisor to A-Pg line): The distance is measured form the facial surface of the lower incisor to the Apogonion line.

## E- Air way Analysis:

1. Upper pharynx (U-PHA): The upper pharyngeal width is measured from a point on the posterior outline of the soft palate to the closest point on the posterior pharyngeal wall.
2. Lower pharynx (L-PHA): Lower pharyngeal width is measured from the intersection of the posterior border of the tongue and the inferior border of the mandible to the closest point on the posterior pharyngeal wall.

## A-Relationship of Maxilla to Cranial Base:

Analysis of variance (ANOVA) showed significant differences at ( $\mathrm{p} \leq 0.001$ ) among variables (NA-P and SNA) measured in Cl . I, Cl. II and Cl. III groups in both males and females, as in Table (4), while Table (5) shows duncan's multiple range test of maxilla relation to cranial base.

## C- Relationship of Mandible to Cranial Base:

Analysis of variance (ANOVA) showed significant differences (at $\mathrm{p} \leq 0.001$ ) in variable ( $\mathrm{Pg}-\mathrm{N}$ ) measured in Cl . I, Cl. II and Cl. III groups in both males and females, as in Table(8), while Table (9) shows duncan's multiple range test of mandible relation to cranial base.

International Journal of Enhanced Research in Science Technology \& Engineering, ISSN: 2319-7463 Vol. 3 Issue 4, April-2014, pp: (287-299), Impact Factor: 1.252, Available online at: www.erpublications.com

## E- Airway Analysis (Airway Patency) :

Analysis of variance (ANOVA) showed no significant differences (at $\mathrm{p} \leq 0.001$ ) in variable (U-PHA) and significant differences (at $\mathrm{p} \leq 0.001$ ) in variable (L-PHA) measured in Cl. I, Cl. II and Cl. III groups in both males and females, as in Table(12), while Table (13) shows duncan's multiple range test of airway analysis.

Table (12): Analysis of Variance of Airway Analysis in CI. I, Cl. II and Cl. III Groups of Both Genders

|  |  | Sum of Squares | df | Mean Square | F | Sig. |

## Discussion

This study aims to establish normal values of McNamara analysis of Mosul city population for both males and females of different skeletal relationships.

## A-Relationship Of Maxilla To Cranial Base:

The results showed no significant differences in position of maxilla in relation to N perpendicular (NA-P distance) between males and females in Cl. I group, this agree with Nahidh ${ }^{(6)}$ who studied McNamara cephalometric analysis among students in Baghdad city. In the other hand, significant differences present among Cl. II group and remaining groups, possibly due to anterior position of point (A) in prognathic maxilla present in Cl. II group.In case of angular position of maxilla relative to sella - nasion plane (SNA angle), no significant differences found between males and females in Cl. I group, this result disagree with Nahidh study ${ }^{(6)}$. While Cl. II group had largest mean which significantly differs from other groups due to anterior position of point A. The results also showed no significant differences in (SNA) angle means among Cl . I and Cl . III groups (males and females), this agree with Mohammed ${ }^{(7)}$.

## B- Relationship Of Mandible To Maxilla:

The results showed effective mandibular length ( $\mathrm{Co}-\mathrm{Gn}$ ) had its largest mean in Cl . III group with no significant differences between males and females, this result may attributed to long mandible present in Cl. III than Cl . I and Cl . II skeletal patterns. Effective midfacial length (Co-A) had its largest mean in Cl. II group with no significant differences between males and females, this large midfacial length lead to maxillary prognathisim and Cl. II malocclusion. Also no significant differences found between males and females in Cl. I group, this result disagree with Nahidh ${ }^{(6)}$ who found males had significantly greater midfacial length than females. Maxillomandibular difference had its significantly greatest mean in Cl. III group, while smallest mean present in Cl. II females subjects, this may be due to anterior rotation of mandibular growth pattern present in Cl. III subjects. Lower anterior facial height (ANS-Me) showed its statistically greatest values in males of Cl. II group, this agree with McNamara ${ }^{(2)}$ who mentioned that if lower anterior facial height is increased, the mandible will appear to be more retrognathic and if this height decreased the mandible will appear to be more prognathic, the same can be conclude from work of Tagawa et al ${ }^{(8)}$ who studied orthopedic correction of Cl. III malocclusion, he found that anterior and posterior vertical dimensions of the face increased significantly after treatment. The results showed Cl. III group had smallest lower facial height. No significant differences found between males and females in Cl. I group.

Mandibular plane angle (MD-P) showed its statistically greatest mean in Cl. II group (no significant differences between males and females), this may be due to short mandible lead to posterior rotation and more obtuse angle. Also results showed no significant differences between males and females subjects of Cl. I group. Facial axis angle (FA-A) had its statistically greatest degree in Cl. III females, while Cl. II males and females had statistically smallest degree (no significant differences between them). McNamara ${ }^{(2)}$ mentioned that excessive vertical development is indicated by negative values (less than 90) while deficient vertical facial development is indicated by positive values (greater than 90), the angle measured is that formed by basion-PTM-gnathion and expected to have perpendicular relationship in a balanced face. In Cl . I group, males had statistically significant higher mean than females, this disagree with Nahidh ${ }^{(6)}$ who found no significant differences present between males and females. In relationship of mandible to maxilla, three variables (Co-A, ANS-Me and MD-P) had no significant differences between males and females in Cl. I group, this agree with Wong et al ${ }^{(9)}$ who studied

McNamara's cephalometric analysis in Chinese using three dimensional cone beam computerized tomography (CBCT) and found no significant differences between males and females for variables relating mandible to maxilla, the remaining three variables that had significant differences between males and females, males always had greater mean's value than females.

## C- Relationship Of Mandible To Cranial Base:

Results showed Cl. III group had pogonion (Pg point) in front of nasion perpendicular in about 2 mm , a prognathic mandible with small mandibular plane angle lead to this forward pogonion position than normal Cl . I balanced face. While Cl. II group had negative reading ( -7 to -8 mm ) behind nasion perpendicular line, this result may caused by retrusive mandible and steep mandibular plane angle ${ }^{(10)}$. In Cl. I group, males had pogonion significantly anteriorly located in relation to nasion perpendicular than females.

## D- Analysis Of Dentition:

Relation of upper incisors to the maxilla: results showed centrals of Cl. II group located more anteriorly in relation to vertical line drawn through point A (parallel to nasion perpendicular) than other groups, with no significant differences between males and females. This perhaps due to more anterior position of alveolar part of maxilla in relation to basal part present in Cl. II group, in the same time protruded centrals and flaring present usually in Cl. II skeletal pattern may be cause this results. In other hand, Cl. III group showed centrals positioned more posteriorly in relation to (A- perpendicular), this retruded centrals may occur due to anterior cross bite ${ }^{(10)}$. Relation of lower incisors to the mandible: results showed lower centrals in Cl. III group located more anteriorly than remaining groups in relation to the reference line ( A- pogonion) with no significant differences between males and females, long protruded mandible and anterior reverse overjet may cause this proclination in lower incisors ${ }^{(10)}$. While Cl. II group (males and females) and Cl. I males showed posterior position of upper centrals in relation to (A-pogonion) line. In both variables of upper and lower incisors there were no significant differences in mean's value between males and females in Cl. I group.

## E- Airway Analysis (Airway Patency) :

Results showed no significant differences among subjects of all groups in upper pharynx measurement, probably due to slight effect of maxilla and mandible on upper pharyngeal width, whoever more studies needed with a three dimensional representation since head film outline of the nasopharynx is a two dimensional representation of a three dimensional structure ${ }^{(2)}$. McNamara mentioned that 5 mm or less in the upper pharyngeal measurement is indicator of possible airway impairments, in this study majority of subjects had upper pharynx measurements located between (11-14) mm with no statistical differences between males and females. Lower pharynx measurements showed Cl. III males and females had widest lower pharyngeal width with no significant differences between them, while (Cl. II F, Cl. I M and Cl. II M) subjects had narrowest width. Cl. III group had long and / or anterior position mandible may lead to anterior tongue position and wide lower pharynx space, also anterior tongue position may happen due to habitual posture or enlargement of the tonsils. More accurate diagnosis about airway impairment can be made only by an otorhinolaryngologist during clinical examination.

## Conclusions

- It would be preferable to use specific norms of McNamara analysis for Mosul city, results showed differences between this study and other studies in Iraq and world.
- In this study, majority of variables had no gender differences in Cl. I group, 8 variables out of 13 total variables measured had no significant differences between males and females.
- Three dimensional representation and clinical examination by otorhinolaryngologist are necessary for complete airway analysis.
